

System Design.

5

LLD → Low Level Design.

on an array if we have to search an element is an "isolated problem" then the Binary Search or Linear Search is the solution to the problem (same with sorting).

If we build an application around the solution of that DSA solution. that is called as LLD.

Area to focus which LLD do.

1) Scalability → When an application scale up to million of users then that thing application sustain that tells you scalability. if we have to update the new feature that take how much ~~of Maintainability~~ → additional work, how easily we scale the application.

2) Maintainability → The code which you have written for the application is basically how maintainable it is. if like we integrate new feature then the part feature doesn't have any issues. and easily debugable. code be

3) Re-usability → The application must be the highly re-usable. The code must not be tightly coupled.

Reusable algorithm. Example.

1) Rider mapping algorithm can be used for / in multiple application.

What is not LLD?

↳ HLD → High Level Design.
purpose of HLD is }
↳ Tech Stack → as application is build on Java / Spring Boot.
→ DB (SQL / NOSQL).
→ Server Scale
→ cost optimization. (deals with low cost).

1) With HLD, LLD and DSA all three we can build the application.

- * HLD focus to System Architecture
- * LLD focus on code structure.
- * DSA is a tool to solve the problem. LLD use.

note point →

If DSA is the Brain of the Application.
LLD is the skeleton.
